REINFORCED PLASTIC CRATE

ABSTRACT

5 A material handling crate having molded plastic side panels and an open top portion reinforced by an endless steel ring extending around the top of the crate and having an exposed upper surface forming at least a portion of the top surface of the rim of the crate.

10 This invention relates to crates, and more particularly to crates having side walls molded from synthetic resin materials and an open top reinforced by a metal ring.

15 The use of material handling crates formed from synthetic resin materials, hereinafter referred to as plastic, is currently expanding very rapidly. This expanded use has been, in part, made possible by the practice of reinforcing the crates adjacent the open top portion by metal rings or bars. This practice has been particularly
20 useful in heavy duty crates or tote boxes such as those employed in the dairy industry or as field crates for vegetables or the like. Numerous arrangements have been devised for reinforcing the top portions of such crates, and one such arrangement is illustrated in my prior U.S. Patent 3,419,182.

25 While the prior art reinforcing schemes have generally been successful, it has been found that they have not been entirely satisfactory for certain uses of heavy duty crates which are normally designed to be stacked one

on top of the other in the manner illustrated, for example, in U.S. Patent 3,361,292. In the prior art crates, the primary purpose of the reinforcing ring has been to provide dimensionall stability for the top of the crate and to
5 reinforce the side panels to enable the crate to withstand lateral loads. While these functions of the reinforcing ring are in most cases essential, it may also be desirable to protect the plastic material at the top rim portion of the crate from damage resulting from impact loads to the
10 top rim during handling, stacking, emptying, or cleaning of the crates. Accordingly, it is the primary object of the present invention to provide an improved reinforced molded plastic crate in which the reinforcing member has an exposed upper surface at the rim of the container to
15 protect the plastic material at the rim.

The foregoing and other objects are obtained in a material handling crate according to present invention, and including molded side walls having integrally formed thereon a generally horizontal ledge extending in vertically
20 spaced relation below the top rim surface of the plastic side walls. An endless steel reinforcing ring is positioned around the crate in contact with the horizontal ledge, with the ring extending above the ledge and terminating in an exposed upper edge surface. The crate is formed with a
25 plurality of openings extending through the plastic walls adjacent the ledge, and a plurality of tabs are integrally formed on the reinforcing rod member in position to extend through the spaced openings providing an interlocking arrangement retaining the reinforcing ring on the crate and in
30 contact with a peripheral edge surface thereof adjacent the rim of the crate.

Other objects and advantages of the invention will become apparent from the following specification, taken with the accompanying drawings, in which:

FIG. 1 is a perspective view of the top portion of a molded plastic crate according to one embodiment of the present invention, with the reinforcing ring in position to be installed on the crate;

FIG. 2 is an enlarged fragmentary sectional view of the reinforcing ring and the crate of FIG. 1 after assembly;

FIG. 3 is a fragmentary elevation view of the structure shown in FIG. 2; and

FIG. 4 is a view similar to FIG. 2 and illustrating an alternate embodiment of the invention.

Referring now to the drawings in detail, the top portion of a reinforced plastic material handling crate according to one embodiment of the present invention is indicated generally by the reference numeral 1 and is shown in FIG. 1 as having four integrally molded, vertically extending plastic side wall panels indicated generally by the reference numerals 2, 3, 4, and 5, respectively. The vertical side panels may each be formed with a plurality of reinforcing, or stiffening ribs 6, as desired, and a handle opening 7 may be formed in the respective side panels in the conventional manner.

The horizontal cross section of the crate chosen for illustrative purposes is substantially rectangular, and, in the embodiment shown in FIGS. 1 - 3, each of the side panels have integrally formed along their upper edge a substantially L-shaped portion 9 including a substantially

5 horizontally extending flange portion 10 and a vertically
extending band portion 11, said flange and band portions
cooperating to define a ledge 12 extending around the
inner periphery of the crate 1 adjacent the top or rim
portion thereof. A plurality of generally rectangular
openings 13 extend horizontally through the band portion 11
at spaced intervals therealong, with at least one, and
preferably two or more openings 13 being positioned inter-
mediate the vertical side edges of each of the respective
10 side panels.

An endless metal reinforcing rod member 15 is
formed from a length of the steel rod shaped into a
generally rectangular configuration by having its adjoining
ends welded as at 16 to form a closed loop. The outer
15 periphery of reinforcing member 15 is substantially equal
to and is shaped to conform to the inner periphery of the
band portion 11 when the lower edge surface 17 of the
reinforcing member is disposed upon the ledge 12. The
inner periphery of reinforcing rod 15 is shaped to form, in
effect, a vertical continuation of the inner side surfaces
20 of the respective side panels, as illustrated in FIG. 2 of
the drawings. A plurality of tabs 18 are integrally formed
on and project laterally from the outer peripheral surface
of reinforcing rod member 15. Preferably tab members 18
25 are formed by coining a portion of the material from the
outer edge of the steel rod. The tabs 18 have a generally
rectangular cross section corresponding to the shape and
size of the openings 13, with the tabs 18 being spaced to
project one through each of the respective openings.

30 Reinforcing rod member 15 is dimensioned such that
its upper edge surface 19 is substantially flush with the

top edge surface of the band 11 so that the reinforcing rod member 15 forms a part of the top rim portion of the crate. In the event of impact loads applied to the top rim of the crate, as by dropping another crate thereon, or by striking the top edge of the crate against a hard surface while emptying or cleaning, the reinforcing rod member 15 will transmit the impact load over a substantial area of the ledge 12 thereby protecting the plastic side walls at the top rim against breaking or excessive damage.

The reinforcing rod member 15 is equally effective in reinforcing the crate for the usual purposes, i.e., providing the dimensional stability for the top of the crate and reinforcing the side walls of the crate against lateral loads, as in the prior art devices. Since the reinforcing rod is dimensioned to fit snugly on the ledge 12 within band 11, the outwardly extending horizontal tabs provide an effective interlock positively retaining the reinforcing rim on the crate. In this respect, it is pointed out that the maximum lateral load normally encountered, by such crates are impact loads from the outer surface rather than pressure loads from the inside; therefore, placing the reinforcing rod element on the inner periphery of the crate provides maximum reinforcing for the crate.

Referring now to FIG. 4 of the drawings, an alternate embodiment of the invention is illustrated in which the inner peripheral surface of the side wall are continuous, and the reinforcing rod retaining ledge 22 is formed by providing an outwardly projecting, substantially horizontal flange 23 extending around the outer periphery of the crate in vertically spaced relation to the top

edge thereof. A plurality of generally rectangular openings 24 are formed in the side walls of the crate between flange 23 and the top peripheral edge thereof, in position to receive a plurality of inwardly extending tab members 25 on an endless reinforcing rod element 26. Tab members 25 are similar to tab members 18 on reinforcing rod member 15, but are formed on the inner rather than the outer periphery of the ring. In this embodiment it is necessary to provide means for preventing the side walls of the crate from being deflected inwardly away from the reinforcing rod member 26. To this end, a plurality of vertically extending generally rectangular openings 27 are formed through the horizontally extending flange 23 in position to receive an equal number of vertically extending tab members 28 integrally formed on and projecting downwardly from the bottom edge of reinforcing rod member 26. Thus, tabs 28 disposed in openings 27, and tabs 25 disposed in opening 24 cooperate to retain reinforcing rod member 26 on the outer periphery of the crate and to prevent deflection of the side walls of the crate under the influence of lateral loads. At the same time, the top edge 29 of reinforcing rod 26 protects the top rim of the crate against impact loads in the manner similar to that described above with regard to the embodiment illustrated in FIGS. 1 - 3. Thus, it is apparent that various modifications of the invention may be made while maintaining the concept of providing an exposed upper surface on the reinforcing rod member which forms a portion of the top rim surface of the crate.

Accordingly, while preferred embodiments of my invention have been disclosed and described, I wish it understood that I do not intend to be restricted solely thereto.

892971

but that I do intend to include all embodiments thereof
which would be apparent to one skilled in the art and which
come within the spirit and scope of my invention.

I CLAIM:

1. In a material handling crate having integrally molded plastic side walls and reinforcing means on said side walls adjacent the open top of the crate, the improvement wherein said reinforcing means comprises an endless metal ring mounted on and extending around said crate adjacent the open top thereof and having an exposed upwardly directed surface defining at least a portion of the top rim surface of the crate, and retaining means supporting said reinforcing ring in position on said crate, said retaining means including integrally molded means on said side walls defining a substantially horizontal ledge positioned to engage and support a downwardly directed surface of said retaining ring, said horizontal ledge being capable of transmitting vertical loads from said reinforcing ring to said side walls, and means interlocking said retaining means and said reinforcing ring to prevent substantial relative movement between said retaining ring and said side walls of said crate.

2. In the material handling crate defined in Claim 1, the further improvement wherein said retaining means comprises a shoulder defined by a substantially horizontal flange extending around said crate adjacent the open top thereof and a band extending upwardly from said flange.

1 3. In the material handling crate defined in
2 Claim 2, the further improvement wherein the top edge surface
3 of said band and said exposed upwardly directed surface
4 cooperating to define the top rim surface of said crate.

1 4. In the material handling crate defined in
2 Claim 2, the further improvement wherein said means inter-
3 locking said retaining means and said reinforcing ring
4 comprises a plurality of openings extending through said
5 retaining means at spaced intervals around said crate, and
6 a plurality of integrally formed tab portions on said rein-
7 forcing ring, said tab means extending through said openings
8 and cooperating with said flange and said web to prevent
9 substantial relative movement therebetween.

1 5. The material handling crate defined in Claim 4,
2 wherein said band extends upwardly from the outer peripheral
3 edge of said flange to define said shoulder for supporting
4 said reinforcing ring around the inner periphery at said
5 crate at said open top.

1 6. The material handling crate defined in Claim 5,
2 wherein said openings extend horizontally through said band
3 and said tabs project outwardly from the outer peripheral
4 surface of said reinforcing ring in position to project one
5 through each of said openings to prevent said reinforcing
6 ring from being lifted vertically from said shoulder.

1 7. The material handling crate defined in Claim 4,
2 wherein said band extends upwardly from the inner peripheral
3 edge of said flange to define said shoulder for supporting
4 said reinforcing ring around the outer periphery of said
5 crate at said open top, said band forming in effect a
6 vertical continuation of said side walls above said flange.

7 8. The material handling crate defined in Claim 7,
8 wherein a portion of said openings are extended horizontally
9 through said band and a portion extend vertically through
10 said flange, said reinforcing ring having a portion of said
tabs extending inward from the inner peripheral surface
thereof to extend through said openings in said band to
prevent vertical movement of said reinforcing ring and a
portion of said tabs extending downward through said
openings in said flange to prevent said side walls from
being deflected inward relative to said reinforcing ring.
